

# KNN:

## Algorithm:

for every point (N)

→ find the distance (d) to every other point (N)

→ sort all those distances ( $N \log N - N^2$ )

→ take the points corresponding to the K-smallest (i) and do majority voting

total TC =  $O(N^3)$

→ suffers from curse of Dimensionality

→ Distance based, no training required.

→ No learnable parameters.

→ Hyperparameter = K

```

#Implementation of GridSearch
grid = {'n_neighbors': np.arange(1, 235),
        'p': np.arange(1, 3),
        'weights': ['uniform', 'distance'],
        'algorithm': ['auto', 'ball_tree', 'kd_tree', 'brute']}

knn = KNeighborsClassifier()
knn_cv = GridSearchCV(knn, grid, cv=3)
knn_cv.fit(X_train, Y_train)

print("Hyperparameters:", knn_cv.best_params_)
print("Train Score:", knn_cv.best_score_)
result_train["GridSearch-Best-Train"] = knn_cv.best_score_

```

```

Hyperparameters: {'algorithm': 'auto', 'n_neighbors': 9, 'p': 1, 'weights': 'distance'}
Train Score: 0.9472667596142674

```

### p

Different distance metrics are available which use for the tree (like KDTree or Ball Tree). One of them is Minkowski metric. This p parameter is power parameter for Minkowski metric.

- If  $p = 1$ , this is equivalent to using `manhattan_distance(L1)`
- If  $p = 2$ , this is equivalent to using `euclidean_distance(L2)`
- If  $p > 2$ , it is `minkowski_distance(Lp)`.

To who wonder what these functions are;

- EuclideanDistance  $\Rightarrow \sqrt{\sum (x - y)^2}$
- ManhattanDistance  $\Rightarrow \sum (|x - y|)$
- MinkowskiDistance  $\Rightarrow \sum (|x - y|^p)^{1/p}$

## KD-Tree:

- K-Dimension Tree is a Space partitioning data structure for organizing points in K-D space.
- similar to BST.
- KD tree are capable of guarantee a depth =  $\log_2(n)$

$n = \#$  points in Dataset

## Approach-1:

### kd-tree example

insert: (30,40), (5,25), (10,12), (70,70), (50,30), (35,45)

- may need balancing → HEAP
- divide space into hypercubeoids in each split.

# Approach-2:

## K-D tree example

- Building a K-D tree from training data:
  - $\{(1,9), (2,3), (4,1), (3,7), (5,4), (6,8), (7,2), (8,8), (7,9), (9,6)\}$
  - pick random dimension, find median, split data, repeat

## K-D tree example

- Building a K-D tree from training data:
  - $\{(1,9), (2,3), (4,1), (3,7), (5,4), (6,8), (7,2), (8,8), (7,9), (9,6)\}$
  - pick random dimension, find median, split data, repeat
- Find NNs for new point (7,4)
  - find region containing (7,4)
  - compare to all points in region

→ median method produces balanced Binary Tree.

→  $\boxed{TC}$ :

- height =  $O(\log n)$
- find median every time =  $O(n)$
- search =  $O(\log n)$
- $\therefore \text{total} = O(n \log^2 n)$
